Ciais et al. (2026): full-text acquisition pending

[Unread]. This is an acquisition record, not a scientific summary. The complete article and supplementary materials have been requested from the user.

Reference. Ciais et al., *Science*, doi:10.1126/science.adx8262. Full bibliographic metadata supplied by the user remain in `methane_surge_comparison.bib`.

Acquisition attempts. Science article and supplementary endpoints returned HTTP 403. The HAL record `hal-05503114` provides bibliographic metadata but no downloadable full text at the checked document endpoint. Author and institutional discovery records were also checked. The supplied Zotero paths refer to a macOS filesystem that is absent on this host.

Required material. Full text and all supplementary files are needed to establish the model design, observational constraints, source and sink definitions, temporal baseline, and availability of posterior data. None of these are reconstructed from the abstract or from another paper's discussion. The report therefore makes no quantitative attribution claim from this study.

Planned use once supplied. Read and summarize the complete methods and results, obtain the associated public flux and sink data, and identify the 2019–2022 subset. If the necessary burden and loss-rate variables are supplied, calculate the native steady-state adjustment with the existing Python functions. If only aggregate attribution numbers are supplied, retain their original definition and document which parts cannot be transformed without additional assumptions. Replace this acquisition record with the requested approximately one-page scientific summary after that work is complete.
