Qu et al. (2022): full-text acquisition pending

[Unread]. This is an acquisition record, not a scientific summary. The full paper and supplement have been requested from the user.

Reference. Qu et al., "Attribution of the 2020 surge in atmospheric methane by inverse analysis of GOSAT observations," *Environmental Research Letters* 17, 094003, doi:10.1088/1748-9326/ac8754. The original bibliography is retained unchanged in the repository.

Acquisition attempts. The IOP article and PDF endpoints returned access challenges. The IOP content host returned HTTP 403 for the article and supplementary-data URLs. OpenAlex and author-publication pages were checked for an accessible copy. A NASA Earth Science Project Office publication entry was retrieved, but its current page supplies a DOI link without an attached PDF. Download attempts are recorded in `data/downloads.jsonl`.

Required material. The complete article and all supplementary files are required before documenting its inversion design, posterior fluxes, OH definition, uncertainty ensemble, or regional attribution. A summary of this study in a later paper is not a substitute for reading its primary methods. No values attributed to this article are inserted into the numerical comparison.

Planned use once supplied. Extract native 2019 and 2020 emissions, OH loss frequencies or matched burden and removal fluxes, soil and other loss terms, and the averaging conventions used to report growth. Rebase all available quantities to 2019 and apply the documented He et al. equation. Preserve differences between annual priors, initialization, and observation sampling when comparing it with Qu et al. (2024). Do not treat the latter as an interchangeable replacement for this unavailable study, and do not infer missing 2021–2022 values by extrapolation.
